1. Did your estimations reflect actual effort?

The story-point estimations provided a reasonable indication of the relative effort required for the work items. The Fibonacci scale helped distinguish smaller tasks such as maintaining donor information from more complex work such as matching compatible nearby donors. Since the lab used a simulated sprint rather than measured development time, the points cannot be treated as exact measures of actual hours. Overall, the estimates were useful for planning and comparing the complexity of the stories.

2. Was your backlog well-prioritized?

Yes. The backlog was organized around the most important functions of the blood bank system. Core inventory and emergency-request functionality was given higher priority because these capabilities are fundamental to handling blood shortages. Donor matching and notification functionality were also included as important parts of the emergency workflow. Prioritization helped determine which stories were selected for the initial sprint.

3. How did the simulated sprint align with the plan?

The sprint simulation demonstrated both planned progress and unfinished work. In Sprint 1, the team completed the inventory stories while some emergency-request and donor-matching work remained unfinished. Those incomplete stories were carried forward to the next sprint. In Sprint 2, most of the remaining stories were completed, while the final notification stories remained for the automatically created next sprint. This showed how Agile planning accommodates incomplete work instead of treating the original sprint plan as fixed.

4. What insights did the burndown chart give about team capacity?

The burndown chart provides a visual view of work remaining during a sprint and makes it easier to compare progress with the expected pace. It can reveal whether work is being completed steadily, whether progress is delayed, or whether the team is finishing work earlier than planned. In this lab, the sprint simulation showed that team capacity should be considered when selecting stories, because carrying unfinished stories into the next sprint indicates that the initial commitment was higher than the work completed within that sprint.

Overall Reflection: This lab demonstrated how functional requirements can be transformed into an Agile backlog, estimated using story points, prioritized, and delivered through Scrum sprints. The sprint simulation also showed the importance of realistic capacity planning and using progress reports such as the burndown chart to understand sprint performance.
